Better sleep reduces COVID-19 risk: real-time meta analysis of 16 studies

@CovidAnalysis, July 2025, Version 19 https://c19early.org/slmeta.html

Abstract

Significantly lower risk is seen for mortality, hospitalization, and cases. 13 studies from 13 independent teams in 6 countries show significant benefit.

Meta analysis using the most serious outcome reported shows 31% [23-39%] lower risk. Results are similar for peer-reviewed studies.

Results are very robust — in exclusion sensitivity analysis 14 of 16 studies must be excluded to avoid finding statistically significant efficacy in pooled analysis.

Studies analyze sleep quality before infection, and use different definitions of sleep quality.

No treatment is 100% effective. Protocols combine safe and effective options with individual risk/benefit analysis and monitoring. All data and sources to reproduce this analysis are in the appendix.

Zhou et al. present another meta analysis for sleep quality, showing significant improvements for mortality, hospitalization, cases, and long COVID with higher quality sleep.

SLEEP FOR COVID-19 — HIGHLIGHTS

Good quality sleep reduces risk with very high confidence for mortality, hospitalization, cases, and in pooled analysis.

17th treatment shown effective in March 2021, now with p = 0.0000000084 from 16 studies.

Real-time updates and corrections with a consistent protocol for 172 treatments. Outcome specific analysis and combined evidence from all studies including treatment delay, a primary confounding factor.

Figure 1. A. Random effects meta-analysis. This plot shows pooled effects, see the specific outcome analyses for individual outcomes. Analysis validating pooled outcomes for COVID-19 can be found below. Effect extraction is pre-specified, using the most serious outcome reported. For details see the appendix. B. Timeline of results in sleep studies. The marked dates indicate the time when efficacy was known with a statistically significant improvement of ≥10% from ≥3 studies for pooled outcomes and one or more specific outcome.

Introduction

Sleep

Sleep can improve the absorption, metabolism, and utilization of nutrients, reduce chronic inflammation, improve cardiovascular health, improve comorbidities, and reduce stress. Sleep is crucial for the proper functioning of the immune system. During sleep, the body produces and releases cytokines and T cells that help fight infections, reduce inflammation, and create immune memory.

Analysis

We analyze all significant studies reporting COVID-19 outcomes as a function of sleep quality and providing adjusted results. Search methods, inclusion criteria, effect extraction criteria (more serious outcomes have priority), all individual study data, PRISMA answers, and statistical methods are detailed in Appendix 1. We present random effects meta-analysis results for all studies, individual outcomes, and peer-reviewed studies.

Results

Table 1 summarizes the results for all studies, for peer-reviewed studies, and for specific outcomes. Figure 2, 3, 4, 5, 6, and 7 show forest plots for random effects meta-analysis of all studies with pooled effects, mortality results, hospitalization, cases, peer reviewed studies, and long COVID.

	Relative Risk	Studies	Patients
All studies	0.69 [0.61-0.77] ****	16	420K
Peer-reviewed	0.71 [0.64-0.79] ****	15	420K
Mortality	0.73 [0.60-0.90] **	4	380K
Hospitalization	0.75 [0.61-0.91] **	3	110K
Cases	0.86 [0.80-0.93] ****	7	40K

Figure 6. Random effects meta-analysis for peer reviewed studies. Effect extraction is pre-specified, using the most serious outcome reported, see the appendix for details. Analysis validating pooled outcomes for COVID-19 can be found below.
Zeraatkar et al. analyze 356 COVID-19 trials, finding no significant evidence that preprint results are inconsistent with peer-reviewed studies. They also show extremely long peer-review delays, with a median of 6 months to journal publication. A six month delay was equivalent to around 1.5 million deaths during the first two years of the pandemic. Authors recommend using preprint evidence, with appropriate checks for potential falsified data, which provides higher certainty much earlier. Davidson et al. also showed no important difference between meta analysis results of preprints and peer-reviewed publications for COVID-19, based on 37 meta analyses including 114 trials.

Figure 7. Random effects meta-analysis for long COVID. Effect extraction is pre-specified, using the most serious outcome reported, see the appendix for details. Analysis validating pooled outcomes for COVID-19 can be found below.

Pooled Effects

Pooled effects are no longer required to show efficacy as of March 2021

This section validates the use of pooled effects for COVID-19, which enables earlier detection of efficacy, however pooled effects are no longer required for sleep as of March 2021. Efficacy is now known based on specific outcomes.

Combining studies is required

For COVID-19, delay in clinical results translates into additional death and morbidity, as well as additional economic and societal damage. Combining the results of studies reporting different outcomes is required. There may be no mortality in a trial with low-risk patients, however a reduction in severity or improved viral clearance may translate into lower mortality in a high-risk population. Different studies may report lower severity, improved recovery, and lower mortality, and the significance may be very high when combining the results. *"The studies reported different outcomes"* is not a good reason for disregarding results. Pooling the results of studies reporting different outcomes allows us to use more of the available information. Logically we should, and do, use additional information when evaluating treatments—for example dose-response and treatment delay-response relationships provide additional evidence of efficacy that is considered when reviewing the evidence for a treatment.

Specific outcome and pooled analyses

We present both specific outcome and pooled analyses. In order to combine the results of studies reporting different outcomes we use the most serious outcome reported in each study, based on the thesis that improvement in the most serious outcome provides comparable measures of efficacy for a treatment. A critical advantage of this approach is simplicity and transparency. There are many other ways to combine evidence for different outcomes, along with additional evidence such as dose-response relationships, however these increase complexity.

Ethical and practical issues limit high-risk trials

Trials with high-risk patients may be restricted due to ethics for treatments that are known or expected to be effective, and they increase difficulty for recruiting. Using less severe outcomes as a proxy for more serious outcomes allows faster and safer collection of evidence.

Validating pooled outcome analysis for COVID-19

For many COVID-19 treatments, a reduction in mortality logically follows from a reduction in hospitalization, which follows from a reduction in symptomatic cases, which follows from a reduction in PCR positivity. We can directly test this for COVID-19.

Analysis of the the association between different outcomes across studies from all 172 treatments we cover confirms the validity of pooled outcome analysis for COVID-19. Figure 8 shows that lower hospitalization is very strongly associated with lower mortality (p < 0.00000000001). Similarly, Figure 9 shows that improved recovery is very strongly associated with lower mortality (p < 0.00000000001). Considering the extremes, Singh et al. show an association between viral clearance and hospitalization or death, with p = 0.003 after excluding one large outlier from a mutagenic treatment, and based on 44 RCTs including 52,384 patients. Figure 10 shows that improved viral clearance is strongly associated with fewer serious outcomes. The association is very similar to Singh et al., with higher confidence due to the larger number of studies. As with Singh et al., the confidence increases when excluding the outlier treatment, from p = 0.000000082 to p = 0.000000033.

Figure 8. Lower hospitalization is associated with lower mortality, supporting pooled outcome analysis.

Figure 9. Improved recovery is associated with lower mortality, supporting pooled outcome analysis.

c19early.org

Figure 8. Improved viral clearance is associated with fewer serious outcomes, supporting pooled outcome analysis.

Pooled outcomes identify efficacy 5 months faster (7 months for RCTs)

Currently, 55 of the treatments we analyze show statistically significant efficacy or harm, defined as \geq 10% decreased risk or >0% increased risk from \geq 3 studies. 88% of these have been confirmed with one or more specific outcomes, with a mean delay of 4.9 months. When restricting to RCTs only, 57% of treatments showing statistically significant efficacy/harm with pooled effects have been confirmed with one or more specific outcomes, with a mean delay of 7.3 months. Figure 11 shows when treatments were found effective during the pandemic. Pooled outcomes often resulted in earlier detection of efficacy.

Limitations

Pooled analysis could hide efficacy, for example a treatment that is beneficial for late stage patients but has no effect on viral clearance may show no efficacy if most studies only examine viral clearance. In practice, it is rare for a nonantiviral treatment to report viral clearance and to not report clinical outcomes; and in practice other sources of heterogeneity such as difference in treatment delay is more likely to hide efficacy.

Summary

Analysis validates the use of pooled effects and shows significantly faster detection of efficacy on average. However, as with all meta analyses, it is important to review the different studies included. We also present individual outcome analyses, which may be more informative for specific use cases.

Discussion

Notes

Zhou et al. present another meta analysis for sleep quality, showing significant improvements for mortality, hospitalization, cases, and long COVID with higher quality sleep.

Perspective

Results compared with other treatments

SARS-CoV-2 infection and replication involves a complex interplay of 100+ host and viral proteins and other factors ⁶⁻ ¹³, providing many therapeutic targets. Over 9,000 compounds have been predicted to reduce COVID-19 risk ¹⁴, either by directly minimizing infection or replication, by supporting immune system function, or by minimizing secondary complications. Sleep can improve the absorption, metabolism, and utilization of nutrients, reduce chronic inflammation, improve cardiovascular health, improve comorbidities, and reduce stress. Sleep is crucial for the proper functioning of the immune system. During sleep, the body produces and releases cytokines and T cells that help fight infections, reduce inflammation, and create immune memory. Figure 12 shows an overview of the results for sleep in the context of multiple COVID-19 treatments, and Figure 13 shows a plot of efficacy vs. cost for COVID-19 treatments.

Figure 12. Scatter plot showing results within the context of multiple COVID-19 treatments. Diamonds shows the results of random effects meta-analysis. 0.6% of 9,000+ proposed treatments show efficacy ¹⁵.

c19early.org

Figure 13. Efficacy vs. cost for COVID-19 treatments.

Conclusion

Sleep can improve the absorption, metabolism, and utilization of nutrients, reduce chronic inflammation, improve cardiovascular health, improve comorbidities, and reduce stress. Sleep is crucial for the proper functioning of the immune system. During sleep, the body produces and releases cytokines and T cells that help fight infections, reduce inflammation, and create immune memory.

Better sleep reduces risk for COVID-19. Significantly lower risk is seen for mortality, hospitalization, and cases. 13 studies from 13 independent teams in 6 countries show significant benefit. Meta analysis using the most serious outcome reported shows 31% [23-39%] lower risk. Results are similar for peer-reviewed studies. Results are very robust — in exclusion sensitivity analysis 14 of 16 studies must be excluded to avoid finding statistically significant efficacy in pooled analysis.

Studies analyze sleep quality before infection, and use different definitions of sleep quality.

Zhou et al. present another meta analysis for sleep quality, showing significant improvements for mortality, hospitalization, cases, and long COVID with higher quality sleep.

Retrospective 468,569 adults in the UK, showing no significant difference in COVID-19 mortality based on sleep quality.

Atceken

Retrospective 221 COVID-19 patients showing an association between high-risk obstructive sleep apnea and COVID-19 severity.

Cloosterman

Analysis of 2,586 participants of a running injury prevention RCT in the Netherlands, showing higher risk of COVID-19 symptoms with sleep disturbance.

Gao

Case control study in China with 105 cases and 210 matched controls, showing COVID-19 cases associated with lack of sleep.

Holt

Prospective survey-based study with 15,227 people in the UK, showing reduced risk of COVID-19 cases with 8 hours sleep, with statistical significance when compared with \geq 9 hours.

Huang

Retrospective 164 COVID-19 patients and 188 controls in China, showing the risk of severe cases associated with lack of sleep.

Jones

FinnGen Mendelian randomization study showing higher risk of COVID-19 mortality, hospitalization, and infection with insomnia.

Kim

Retrospective 2,884 high-risk healthcare workers in France, Germany, Italy, Spain, UK, and the USA, showing shorter sleep duration associated with increased risk of COVID-19 cases and severity.

Li

UK Biobank retrospective, 46,535 participants with sleep behavior assessed between 2006 and 2010, showing higher risk of hospitalization and mortality with poor sleep.

Retrospective 5,197 Greek adults over 65. After adjustment for confounders, COVID-19 infection was independently associated with poor sleep, low physical activity, low Mediterranean diet adherence, living in urban areas, smoking, obesity, depression, anxiety, stress, and poor health-related quality of life.

Pływaczewska-Jakubowska

Retrospective 1,847 COVID+ patients in Poland, showing lower moderate/severe cases with improved sleep, without statistical significance. Hospitalized patients were excluded.

Wang

Prospective study of 68,896 UK Biobank participants with COVID-19 showing adherence to a healthy lifestyle prior to infection, characterized by 10 factors including adequate physical activity and sleep, not smoking, and a healthy BMI, was associated with a significantly lower risk of mortality, hospitalization, and post-COVID multisystem sequelae. Risk decreased monotonically for increasing numbers of healthy lifestyle factors from 5-10. Reduced risks were evident

across cardiovascular, metabolic, neurologic, respiratory, and other disorders over 210 days following infection, during both acute and post-acute phases, regardless of age, sex, ethnicity, test setting, vaccination status, or SARS-CoV-2 variant.

Wang

Retrospective 1,979 nurses in the USA, showing lower risk of long COVID with better sleep quality.

Appendix 1. Methods and Data

We perform ongoing searches of PubMed, medRxiv, Europe PMC, ClinicalTrials.gov, The Cochrane Library, Google Scholar, Research Square, ScienceDirect, Oxford University Press, the reference lists of other studies and metaanalyses, and submissions to the site c19early.org. Search terms are sleep AND COVID-19. Automated searches are performed twice daily, with all matches reviewed for inclusion. All studies regarding the use of sleep for COVID-19 that report a comparison with a control group are included in the main analysis. Studies with major unexplained data issues, for example major outcome data that is impossible to be correct with no response from the authors, are excluded. This is a living analysis and is updated regularly.

We extracted effect sizes and associated data from all studies. If studies report multiple kinds of effects then the most serious outcome is used in pooled analysis, while other outcomes are included in the outcome specific analyses. For example, if effects for mortality and cases are reported then they are both used in specific outcome analyses, while mortality is used for pooled analysis. If symptomatic results are reported at multiple times, we use the latest time, for example if mortality results are provided at 14 days and 28 days, the results at 28 days have preference. Mortality alone is preferred over combined outcomes. Outcomes with zero events in both arms are not used, the next most serious outcome with one or more events is used. For example, in low-risk populations with no mortality, a reduction in mortality with treatment is not possible, however a reduction in hospitalization, for example, is still valuable. Clinical outcomes are considered

Figure 14. Mid-recovery results can more accurately reflect efficacy when almost all patients recover. *Mateja* et al. confirm that intermediate viral load results more accurately reflect hospitalization/death.

more important than viral outcomes. When basically all patients recover in both treatment and control groups, preference for viral clearance and recovery is given to results mid-recovery where available. After most or all patients have recovered there is little or no room for an effective treatment to do better, however faster recovery is valuable. An IPD meta-analysis confirms that intermediate viral load reduction is more closely associated with hospitalization/death than later viral load reduction ¹⁶. If only individual symptom data is available, the most serious symptom has priority, for example difficulty breathing or low SpO₂ is more important than cough. When results

provide an odds ratio, we compute the relative risk when possible, or convert to a relative risk according to *Zhang et al.* Reported confidence intervals and *p*-values are used when available, and adjusted values are used when provided. If multiple types of adjustments are reported propensity score matching and multivariable regression has preference over propensity score matching or weighting, which has preference over multivariable regression. Adjusted results have preference over unadjusted results for a more serious outcome when the adjustments significantly alter results. When needed, conversion between reported *p*-values and confidence intervals followed *Altman*, *Altman* (*B*), and Fisher's exact test was used to calculate *p*-values for event data. If continuity correction for zero values is required, we use the reciprocal of the opposite arm with the sum of the correction factors equal to 1^{20} . Results are expressed with RR < 1.0 favoring treatment, and using the risk of a negative outcome when applicable (for example, the risk of death rather than the risk of survival). If studies only report relative continuous values such as relative times, the ratio of the time for the treatment group versus the time for the control group is used. Calculations are done in Python (3.13.5) with scipy (1.16.0), pythonmeta (1.26), numpy (2.3.1), statsmodels (0.14.4), and plotly (6.2.0).

Forest plots are computed using PythonMeta²¹ with the DerSimonian and Laird random effects model (the fixed effect assumption is not plausible in this case) and inverse variance weighting. Results are presented with 95% confidence intervals. Heterogeneity among studies was assessed using the l² statistic. Mixed-effects meta-regression results are computed with R (4.4.0) using the metafor (4.6-0) and rms (6.8-0) packages, and using the most serious sufficiently powered outcome. For all statistical tests, a *p*-value less than 0.05 was considered statistically significant. Grobid 0.8.2 is used to parse PDF documents.

We have classified studies as early treatment if most patients are not already at a severe stage at the time of treatment (for example based on oxygen status or lung involvement), and treatment started within 5 days of the onset of symptoms. If studies contain a mix of early treatment and late treatment patients, we consider the treatment time of patients contributing most to the events (for example, consider a study where most patients are treated early but late treatment patients are included, and all mortality events were observed with late treatment patients). We note that a shorter time may be preferable. Antivirals are typically only considered effective when used within a shorter timeframe, for example 0-36 or 0-48 hours for oseltamivir, with longer delays not being effective^{22,23}.

We received no funding, this research is done in our spare time. We have no affiliations with any pharmaceutical companies or political parties.

A summary of study results is below. Please submit updates and corrections at https://c19early.org/slmeta.html.

Prophylaxis

Effect extraction follows pre-specified rules as detailed above and gives priority to more serious outcomes. For pooled analyses, the first (most serious) outcome is used, which may differ from the effect a paper focuses on. Other outcomes are used in outcome specific analyses.

Ahmadi, 8/31/2021, retrospective, United Kingdom, peer-reviewed, 5 authors.	risk of death, 3.0% lower, RR 0.97, <i>p</i> = 0.91, adjusted per study, good vs. poor, model 2, multivariable.
Atceken, 10/26/2024, retrospective, Germany, peer- reviewed, 4 authors.	risk of severe case, 67.4% lower, OR 0.33, <i>p</i> = 0.01, higher quality sleep 39, lower quality sleep 182, inverted to make OR<1 favor higher quality sleep, RR approximated with OR.
Cloosterman, 10/21/2020, retrospective, Netherlands, peer-reviewed, 4 authors.	risk of symptomatic case, 31.6% lower, RR 0.68, $p = 0.09$, higher quality sleep 31 of 201 (15.4%), lower quality sleep 222 of 2,385 (9.3%), inverted to make RR<1 favor higher quality sleep, odds ratio converted to relative risk.
Gao, 11/5/2020, retrospective, China, peer- reviewed, survey, median age 55.0, 11 authors, study period 10 February, 2020 - 1 March, 2020.	risk of case, 35.9% lower, HR 0.64, $p = 0.04$, higher quality sleep 73 of 105 (69.5%) cases, 179 of 210 (85.2%) controls, NNT 4.6, inverted to make HR<1 favor higher quality sleep, case control OR, Cox proportional hazards.

Holt, 3/30/2021, prospective, United Kingdom, peer-reviewed, 34 authors, study period 1 May, 2020 - 5 February, 2021, trial NCT04330599	risk of case, 12.3% lower, OR 0.88, $p = 0.50$, adjusted per study, inverted to make OR<1 favor higher quality sleep, fully adjusted, 8 hours vs. ≤ 6 hours, RR approximated with OR.
(history) (COVIDENCE UK).	risk of case, 12.3% lower, OR 0.88, <i>p</i> = 0.33, adjusted per study, inverted to make OR<1 favor higher quality sleep, fully adjusted, 8 hours vs. 7 hours, RR approximated with OR.
	risk of case, 22.5% lower, OR 0.78, <i>p</i> = 0.04, adjusted per study, inverted to make OR<1 favor higher quality sleep, fully adjusted, 8 hours vs. ≥9 hours, RR approximated with OR.
Huang, 11/30/2021, retrospective, China, peer- reviewed, survey, 5 authors, study period 10 February, 2020 - 28 March, 2020.	risk of severe case, 80.9% lower, RR 0.19, $p = 0.02$, higher quality sleep 12 of 127 (9.4%), lower quality sleep 4 of 9 (44.4%), NNT 2.9, adjusted per study, inverted to make RR<1 favor higher quality sleep, odds ratio converted to relative risk, recommended vs. lack of sleep, multivariable.
Jones, 7/21/2022, retrospective, multiple countries, peer-reviewed, 12 authors.	risk of death, 39.0% lower, OR 0.61, <i>p</i> = 0.001, inverted to make OR<1 favor higher quality sleep, RR approximated with OR.
	risk of hospitalization, 32.0% lower, OR 0.68, <i>p</i> < 0.001, inverted to make OR<1 favor higher quality sleep, RR approximated with OR.
	risk of case, 7.4% lower, OR 0.93, <i>p</i> = 0.04, inverted to make OR<1 favor higher quality sleep, RR approximated with OR.
Kim, 3/22/2021, retrospective, multiple countries, peer-reviewed, survey, mean age 48.0, 8 authors,	risk of moderate/severe case, 17.0% lower, OR 0.83, <i>p</i> = 0.03, per extra hour of sleep, RR approximated with OR.
study period 17 July, 2020 - 25 September, 2020.	risk of case, 11.0% lower, OR 0.89, <i>p</i> = 0.003, per extra hour of sleep, model 3, RR approximated with OR.
Li, 6/18/2021, retrospective, USA, peer-reviewed, mean age 69.4, 8 authors, study period March 2020 - December 2020.	risk of death, 43.2% lower, OR 0.57, <i>p</i> = 0.02, inverted to make OR<1 favor higher quality sleep, fully adjusted model C, significant poor sleep burden, RR approximated with OR.
	risk of hospitalization, 35.9% lower, OR 0.64, <i>p</i> = 0.008, inverted to make OR<1 favor higher quality sleep, fully adjusted model C, significant poor sleep burden, RR approximated with OR.
	risk of hospitalization, 21.3% lower, OR 0.79, $p = 0.02$, inverted to make OR<1 favor higher quality sleep, fully adjusted model C, moderate poor sleep burden, RR approximated with OR.
Marcus, 6/17/2021, prospective, multiple countries, peer-reviewed, survey, 12 authors, study period 26 March, 2020 - 3 May, 2020.	risk of symptomatic case, 16.0% lower, OR 0.84, <i>p</i> < 0.001, adjusted per study, per extra hour sleep, multivariable, RR approximated with OR.
Mohsin, 9/30/2021, retrospective, Bangladesh, peer-reviewed, survey, 10 authors, study period November 2020 - April 2021.	risk of severe case, 37.9% lower, RR 0.62, <i>p</i> < 0.001, higher quality sleep 327 of 948 (34.5%), lower quality sleep 273 of 552 (49.5%), NNT 6.7, adjusted per study, inverted to make RR<1 favor higher quality sleep, odds ratio converted to relative risk, sleep disturbance, multivariable.
Paul, 4/13/2022, retrospective, United Kingdom, preprint, survey, 2 authors.	risk of long COVID, 67.3% lower, RR 0.33, <i>p</i> < 0.001, adjusted per study, inverted to make RR<1 favor higher quality sleep, odds ratio converted to relative risk, very good/good vs. not good/very poor, multivariable, model 4, control prevalance approximated with overall prevalence.

	risk of long COVID, 54.0% lower, RR 0.46, $p = 0.002$, adjusted per study, inverted to make RR<1 favor higher quality sleep, odds ratio converted to relative risk, very good/good vs. average, multivariable, model 4, control prevalance approximated with overall prevalence.
Pavlidou, 11/9/2023, retrospective, Greece, peer- reviewed, 14 authors.	risk of case, 40.5% lower, OR 0.60, $p = 0.01$, higher quality sleep 3,345, lower quality sleep 1,852, adjusted per study, inverted to make OR<1 favor higher quality sleep, adequate vs. inadequate sleep, multivariable, RR approximated with OR.
Pływaczewska-Jakubowska, 10/24/2022, retrospective, Poland, peer-reviewed, median age 51.0, 5 authors, study period May 2020 - January 2022.	risk of moderate/severe case, 17.4% lower, OR 0.83, <i>p</i> = 0.06, higher quality sleep 1,225, lower quality sleep 622, adjusted per study, inverted to make OR<1 favor higher quality sleep, higher quality sleep vs. insomnia or falling asleep after midnight or nightshifts, multivariable, model 3, RR approximated with OR.
	risk of PASC, 7.4% lower, OR 0.93, $p = 0.51$, higher quality sleep 1,015, lower quality sleep 502, adjusted per study, inverted to make OR<1 favor higher quality sleep, higher quality sleep vs. insomnia or falling asleep after midnight or nightshifts, multivariable, model 3, RR approximated with OR.
Wang, 1/31/2024, prospective, United Kingdom, peer-reviewed, 10 authors.	risk of death, 19.0% lower, HR 0.81, <i>p</i> < 0.001, higher quality sleep 50,777, lower quality sleep 18,119, adjusted per study, 7-9 hrs vs. <7 or >9, multivariable.
	risk of hospitalization, 15.0% lower, HR 0.85, <i>p</i> < 0.001, higher quality sleep 50,777, lower quality sleep 18,119, adjusted per study, 7-9 hrs vs. <7 or >9, multivariable.
	risk of PASC, 23.0% lower, HR 0.77, <i>p</i> < 0.001, higher quality sleep 50,777, lower quality sleep 18,119, adjusted per study, 7-9 hrs vs. <7 or >9, multivariable.
Wang (B), 5/30/2023, retrospective, USA, peer- reviewed, 6 authors.	risk of PASC, 36.0% lower, RR 0.64, <i>p</i> < 0.001, higher quality sleep 559, lower quality sleep 180, adjusted per study, healthy sleep before and during the pandemic, multivariable.
	risk of PASC, 18.0% lower, RR 0.82, <i>p</i> = 0.03, adjusted per study, healthy sleep during the pandemic, multivariable.
	risk of PASC, 30.0% lower, RR 0.70, $p = 0.02$, higher quality sleep 238, lower quality sleep 166, adjusted per study, healthy sleep before the pandemic, sleep score 5 vs. score 0 or 1, multivariable.
